THERMODYNAMIC AND TRANSPORT PROPERTIES FOR THE

by Roger A. Svehla and Richard S. Brokaw

Lewis Research Center

SUMMARY

Thermodynamic and transport properties, including enthalpy, entropy, heat capacity, molecular weight, viscosity, and thermal conductivity, have been calculated for the $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$ equilibrium and also the $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2 \rightleftharpoons 2\text{NO} + \text{O}_2$ equilibrium from 300° to 1280° K and from 0.01 to 100 atmospheres. The Prandtl number, Lewis number, isentropic exponent, and two derivatives involving the molecular weight, pressure, and temperature were also calculated. The Chapman-Enskog theory of monatomic gases was applied in the transport property calculations, with an Eucken-type correction to the thermal conductivity to account for internal degrees of freedom. An expression for the thermal conductivity due to chemical reaction was also included. The transport cross sections were calculated for the Lennard-Jones (12-6) potential, the parameters being obtained from analysis of experimental viscosity and thermal conductivity data. Also included in the calculations is a parameter, which may be useful in analyzing to what extent chemical reaction in the gas phase affects thermal conduction. This parameter is tabulated over the same pressure and temperature range over which the thermodynamic and transport properties were calculated.

INTRODUCTION

The dissociation of N_2O_4 has been of interest in heat-transfer studies because the effects of chemical reaction in the gas phase occur at pressures and temperatures convenient for experimental work (refs. 1 to 7). The chemical reactions describing the dissociation from the boiling point of N_2O_4 (294.3° K) to about 1300° K are given by

Reaction I goes essentially to completion before reaction II becomes important. At about 1300° K the NO begins to decompose.

Previous calculations are available for the thermodynamic and transport properties for this system (refs. 6 and 8). However, these previous calculations are for only a pressure of 1 atmosphere (ref. 8) or do not include the NO₂ dissociation (ref. 6). Furthermore, new measurements of the viscosity have become available (ref. 9), allowing more accurate estimates of the interaction potentials, and from these potentials improved transport property calculations. Therefore, thermodynamic and transport properties have been calculated over a wide pressure range (0.01 to 100 atm) and up to 1280° K, at which point the NO₂ is almost completely dissociated. Frozen and equilibrium properties have been calculated, first assuming only reaction I occurs, and second assuming both reactions I and II occur.

EXPERIMENTAL DATA ANALYSIS

Experimental measurements have been reported on both the viscosity and thermal conductivity from room temperature to almost 500° K (refs. 9 to 12), the temperature range where reaction I is predominant. However, the experimental viscosity data of the various workers has shown some large differences. Therefore, the data of the various authors were analyzed in terms of rigorous transport theory for the viscosity of gas mixtures (ref. 13) in order to clarify these differences. The analysis consisted of fitting the experimental viscosity data to the Lennard-Jones (12-6) potential, using the derived constants to calculate both the viscosity and the thermal conductivity, and then comparing the experimental and calculated results. When possible, the derived constants were compared to constants of other molecules of similar size and shape. The constants derived from the experimental viscosity data of Petker and Mason (ref. 9) appeared to be the most reasonable when compared to constants of similar molecules. Furthermore, better agreement between the experimental and calculated viscosity data was found for the data of Petker and Mason than for the experimental viscosity data of references 10 and 11. That is, the constants obtained from the data of reference 9 more closely reproduced the experimental data from which they were derived than did the constants obtained from the data of references 10 and 11.

In the analysis two cases were considered. The gas was assumed to be composed of (1) an equilibrium mixture of NO₂ and N₂O₄ and (2) an equilibrium mixture of NO₂, N₂O₄, NO, and O₂.

The force constants for the N₂O₄ ⇌ 2NO₂ equilibrium system were determined by the following procedure. For the N₂O₄-N₂O₄ interaction ϵ/k was estimated from the following relationship (ref. 14):

$$\frac{\epsilon}{k} = 1.18 T_b \quad (1)$$

(Symbols are defined in appendix A.) For the $\text{NO}_2\text{-NO}_2$ interaction ϵ/k was assigned four trial values of 190, 210, 230, and 250. This range of 190 to 250 for ϵ/k was selected because it encompassed the range considered reasonable for $(\epsilon/k)_{\text{NO}_2\text{-NO}_2}$. For each trial value $(\epsilon/k)_{\text{NO}_2\text{-N}_2\text{O}_4}$ was determined by the usual combining rule (ref. 13)

$$\left(\frac{\epsilon}{k}\right)_{12} = \sqrt{\left(\frac{\epsilon}{k}\right)_{11} \left(\frac{\epsilon}{k}\right)_{22}} \quad (2)$$

For each trial value the three corresponding values of σ , namely, $\sigma_{\text{NO}_2\text{-NO}_2}$, $\sigma_{\text{NO}_2\text{-N}_2\text{O}_4}$, and $\sigma_{\text{N}_2\text{O}_4\text{-N}_2\text{O}_4}$ were determined simultaneously by a least-squares fit of the experimental viscosity data. The best set of constants (in a least squares sense) was then selected from among the four sets. The entire procedure was then repeated, the only difference being that $\sigma_{\text{NO}_2\text{-N}_2\text{O}_4}$ was determined from the combining rule (ref. 13)

$$\sigma_{12} = \frac{1}{2} (\sigma_{11} + \sigma_{22}) \quad (3)$$

That is, only $\sigma_{\text{NO}_2\text{-NO}_2}$ and $\sigma_{\text{N}_2\text{O}_4\text{-N}_2\text{O}_4}$ were determined by a simultaneous least-squares fit of the viscosity data, and $\sigma_{\text{NO}_2\text{-N}_2\text{O}_4}$ was subject to the constraint of equation (3). The best set of constants among these four was then selected. This then completed the analysis of the $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$ equilibrium.

Next the $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO} + \text{O}_2$ equilibrium system was examined. For this system force constant for the $\text{NO}_2\text{-NO}_2$, $\text{NO}_2\text{-N}_2\text{O}_4$, and $\text{N}_2\text{O}_4\text{-N}_2\text{O}_4$ interactions were determined the same way as for the $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$ system. Now, however, force constants for the additional interactions $\text{NO}\text{-NO}$, $\text{O}_2\text{-O}_2$, $\text{NO}_2\text{-NO}$, $\text{NO}_2\text{-O}_2$, $\text{N}_2\text{O}_4\text{-NO}$, $\text{N}_2\text{O}_4\text{-O}_2$, and $\text{NO}\text{-O}_2$ were also needed. For the $\text{NO}\text{-NO}$ and $\text{O}_2\text{-O}_2$ interactions the force constants given in reference 14 were used. These particular constants were determined from experimental viscosity data of pure NO and O₂. In each case the experimental viscosity data used in reference 14 covered a temperature range very nearly the same as that considered herein, and therefore the derived constants should be appropriate for the present calculations. For the other five unlike interactions ($\text{NO}_2\text{-NO}$, $\text{NO}_2\text{-O}_2$, $\text{N}_2\text{O}_4\text{-NO}$, $\text{N}_2\text{O}_4\text{-O}_2$ and $\text{NO}\text{-O}_2$) the combining rules, equations (2) and (3), were used.

Therefore, four different situations were examined, the equilibrium $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$

system, the equilibrium $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2 \rightleftharpoons 2\text{NO} + \text{O}_2$ system, and for each equilibrium two methods of determining $\sigma_{\text{NO}_2-\text{N}_2\text{O}_4}$.

The results showed that a slightly better fit to the viscosity data was obtained by assuming only reaction I occurred. This was found to be true for $\sigma_{\text{NO}_2-\text{N}_2\text{O}_4}$ obtained from the combining rule and also for $\sigma_{\text{NO}_2-\text{N}_2\text{O}_4}$ obtained by least squares. This would suggest that reaction II had not appreciably progressed to the right during the course of the experimental measurements. This notion is supported by experimental kinetic data (refs. 15 to 17), which indicate that the rate of decomposition of NO_2 is rather slow and becomes appreciable only at the highest temperatures and pressures considered by Petker and Mason. (Their experimental viscosity data covered the range 0.5 to 5 atm and 25° to 170° C.) However, even for the condition most favorable for decomposition from thermodynamic considerations (0.5 atm and 170° C), at equilibrium only 2 percent of the NO_2 is decomposed, and for the condition most favorable from kinetic considerations, (5 atm and 170° C) NO_2 decomposition is only 1 percent. Therefore, since it is known that reaction I reaches equilibrium very rapidly, the constants derived assuming an equilibrium mixture of $\text{NO}_2-\text{N}_2\text{O}_4$ were considered the more realistic Lennard-Jones (12-6) parameters and were used in the calculations herein.

In order to compare the two methods of determining $\sigma_{\text{NO}_2-\text{N}_2\text{O}_4}$, transport properties were calculated using the $\sigma_{\text{NO}_2-\text{N}_2\text{O}_4}$ determined by both methods. Necessarily the value obtained by least squares gave a better fit to the viscosity data. The improvement was so slight, however, that the $\sigma_{\text{NO}_2-\text{N}_2\text{O}_4}$ determined by least squares could not be judged a better value. The thermal conductivity data calculated for each $\sigma_{\text{NO}_2-\text{N}_2\text{O}_4}$

TABLE I. - LENNARD-JONES (12-6) POTENTIAL FORCE CONSTANTS FOR
THE NO- $\text{NO}_2-\text{O}_2-\text{N}_2\text{O}_4$ SYSTEM

Interaction	σ , Å	ϵ/k , °K	Method of determination of σ and ϵ/k
NO-NO	3.492	116.7	Ref. 14
NO- NO_2	3.628 ₅	156.5	Eqs. (2) and (3)
NO- N_2O_4	4.056 ₅	201.2	Eqs. (2) and (3)
NO- O_2	3.479 ₅	111.6	Eqs. (2) and (3)
NO_2-NO_2	3.765	210	Least-squares fit of viscosity data for σ and ϵ/k
$\text{NO}_2-\text{N}_2\text{O}_4$	4.193	270	Eqs. (2) and (3)
NO_2-O_2	3.616	149.7	Eqs. (2) and (3)
$\text{N}_2\text{O}_4-\text{N}_2\text{O}_4$	4.621	347	Least-squares fit of viscosity data for σ and eq. (1) for ϵ/k
$\text{N}_2\text{O}_4-\text{O}_2$	4.044	192.4	Eqs. (2) and (3)
O_2-O_2	3.467	106.7	Ref. 14

were also compared. Since the contribution of the thermal conductivity due to chemical reaction is particularly sensitive to the unlike interactions, comparison of the calculated conductivity data should provide a critical test of the relative merits of the two $\sigma_{\text{NO}_2-\text{N}_2\text{O}_4}$. As was found for the viscosity, however, the two sets of calculations were in close agreement. Therefore, in order to be consistent with the method of determining the constants of the other unlike interactions and to minimize the number of adjustable parameters, $\sigma_{\text{NO}_2-\text{N}_2\text{O}_4}$ was calculated by equation (3).

Table I gives a summary of the force constants used in the calculations herein and the method of determining each.

When compared to constants of similar molecules, such as N_2O and CO_2 , the constants for NO_2 appear reasonable. However, since it was found in the analysis that there was a range of sets of force constants, which reproduced the experimental viscosity data about equally well, these constants should not be considered the "true" constants, but merely as suitable ones, which will reproduce the experimental data about as well as, or better than, any other set.

As expected, the constants for N_2O_4 are substantially larger than those for NO_2 . An approximate value of $\sigma_{\text{N}_2\text{O}_4}$ can be estimated from the boiling point density. Using equations proposed in references 13 ($2/3 \pi N\sigma^3 = 2.0 V_b$) and 14 ($2/3 \pi N\sigma^3 = 2.0 V_b - 5$), and a boiling point density of 1.443 (interpolated from N_2O_4 liquid densities given in refs. 18 and 19), gives values of σ of 4.66 and 4.60, respectively. Since the value given in table I lies between these two, it does appear to be reasonable.

CALCULATION OF PROPERTIES

The thermodynamic and transport properties were calculated using the program described in reference 20. Calculations were performed for both the equilibrium $\text{NO}_2-\text{N}_2\text{O}_4$ system and the equilibrium $\text{NO}_2-\text{N}_2\text{O}_4-\text{NO}-\text{O}_2$ system from 300° to 1280° K and from 0.01 to 100 atmospheres. The properties designated as frozen are for the equilibrium composition at the corresponding temperature and pressure.

Briefly, the rigorous Chapman-Enskog theory for gas mixtures was applied for the transport property calculations herein. Though the theory assumes only binary collisions of monatomic gases, it has been shown to apply satisfactorily to the viscosity of mixtures of polyatomic gases as well as to the viscosity and thermal conductivity of mixtures of monatomic gases (ref. 21). For the thermal conductivity the contribution of the translational conductivity was calculated from the theory which is rigorous for a mixture of monatomic gases. A modified Eucken-type expression was added to account for the contribution of the internal energy states, and the thermal conductivity due to chemical reaction was calculated from the equation developed in references 22 and 23.

TABLE II. - STANDARD STATE (ZERO PRESSURE)

ENTHALPIES AT 0° AND 298.15° K (REF. 26)

Molecule	Standard state enthalpy, H_T^0 , cal/g-mole	
	H_0^0	$H_{298.15}^0$ (a)
NO	19 402.955	21 600.000
NO ₂	5 570.344	8 007.475
N ₂ O ₄	-1 569.312	2 348.836
O ₂	-2 074.739	0

^aValues at 298.15° K are also heats of formation at this temperature.

The transport cross sections were all calculated for the Lennard-Jones (12-6) potential and included the third approximation for the viscosity (ref. 13). The force constants for the various interactions have been summarized in table I.

The details of the thermodynamic property calculations may be found in references 24 and 25. Values of standard state enthalpies of the pertinent molecules are given in table II for convenience in converting enthalpies to a different reference value.

DISCUSSION OF RESULTS

The thermodynamic and transport properties are given in tables III and IV, respectively. Equilibrium properties, for reaction I have been calculated for 0.01, 0.1, 1, 10, and 100 atmospheres from 300° to 1280° K at 20° K intervals. Properties designated as frozen are for the equilibrium composition. Similar calculations are also included for pressures of 0.01, 0.03, 0.1, 0.3, 1, 3, 10, 30, and 100 atmospheres, assuming both reactions I and II occur.

The thermodynamic properties of table III are in substantial agreement with the data of Brokaw (ref. 6) and Fan and Mason (ref. 8). However, the viscosity and thermal conductivity data of table IV are somewhat higher than the calculated data of reference 6; they are also higher than that of reference 8 in the lower temperature region, where NO₂ and N₂O₄ are the predominant constituents. These differences in the transport properties are attributed to the differences in the Lennard-Jones (12-6) force constants used in the calculations, especially the constants for the NO₂-NO₂ and N₂O₄-N₂O₄ interactions. Whereas the force constants used herein were obtained from the experimental data of reference 9, the data of references 6 and 8 were calculated using estimated constants (ref. 6) for the NO₂-NO₂ and N₂O₄-N₂O₄ interactions. The viscosities calculated from these estimated constants are lower than the experimental data of Petker and Mason (ref. 9). At the higher temperatures the NO₂ is dissociated into NO and O₂. Since the force constants used in reference 8 for the NO-NO and O₂-O₂ interactions and those used in the calculation of table IV are about the same, the transport properties are in substantial agreement at the higher temperatures.

Table V, given in appendix B, presents values of a chemical kinetic parameter φ

for the $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$ and $2\text{NO}_2 \rightleftharpoons 2\text{NO} + \text{O}_2$ reactions. This parameter indicates the extent to which gas phase chemical reaction affects thermal conduction or heat transfer in reacting gas systems. It is defined as

$$\varphi \equiv \left[\left(\frac{\lambda_e}{\lambda_r \lambda_f} \right) \left(\frac{\Delta H}{RT} \right)^2 R \dot{R} \right]^{1/2} \quad (4)$$

where \dot{R} is the reaction rate in either direction at equilibrium and ΔH is the heat of reaction at temperature T . The calculation of this parameter is discussed in appendix B.

The dimensionless quantity $(\varphi l)^2$, where l is a dimension characteristic of the system, involves among other things a ratio of a diffusion time to a chemical relaxation time (ref. 27). Consequently, it is closely related to Damköhler's first group, which is the ratio of a time associated with a flow to a chemical time.

The values of φ from table V (p. 19) have been used to correct the experimentally

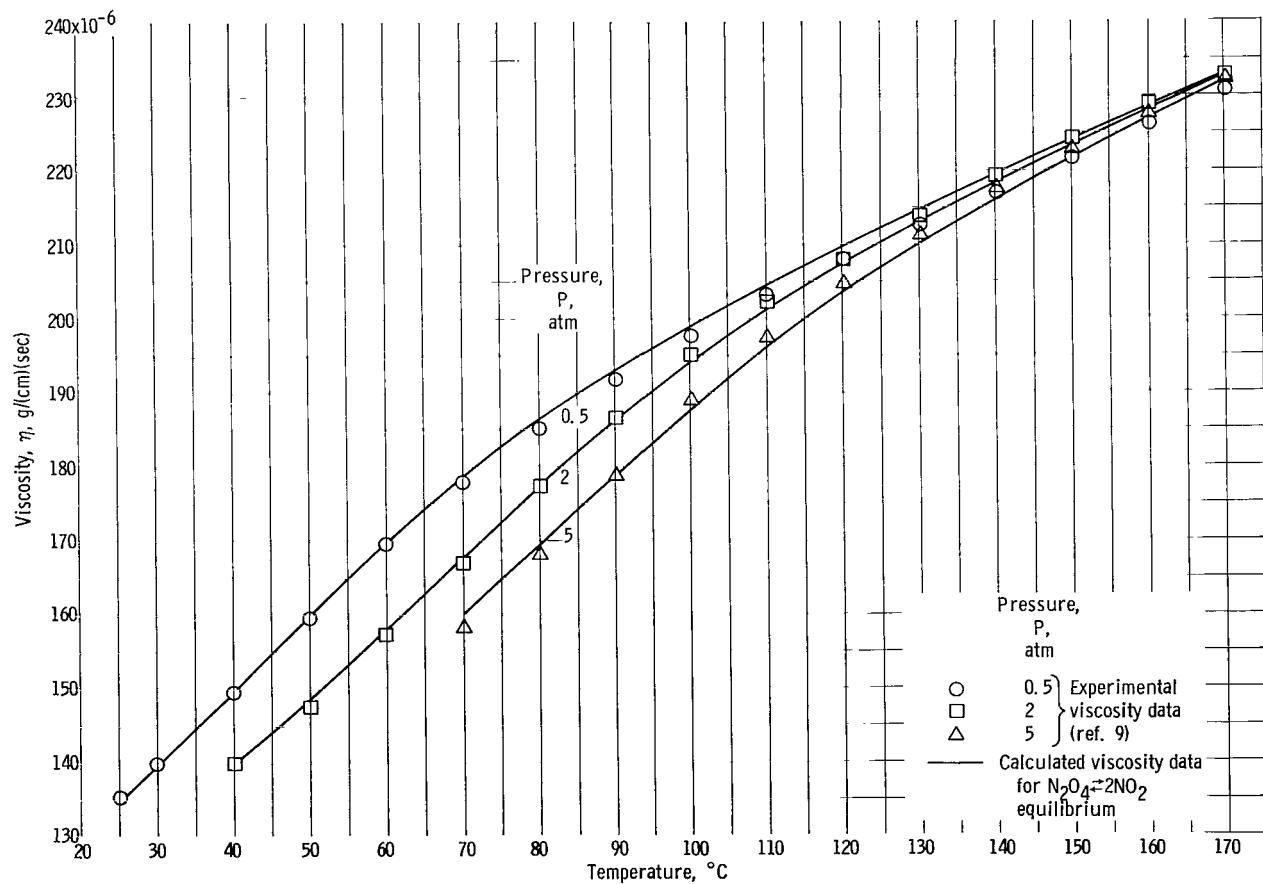

Figure 1. - Experimental and calculated viscosity as a function of temperature.

observed heat conductivities for the $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$ system to equilibrium values, as described in appendix B. Appendix C provides an example of how the chemical kinetic parameter φ may be useful in predicting convective heat transfer in situations where the chemistry is neither completely at equilibrium nor completely frozen.

Figure 1 (p. 7) shows the calculated viscosity data, assuming the equilibrium $\text{NO}_2\text{-N}_2\text{O}_4$ mixture, at pressures of 0.5, 2, and 5 atmospheres from 25° to 170° C. Also included are the experimental data of reference 9. Experimental data at 1 and 3 atmospheres are also reported in reference 9, but these data were not included in figure 1 because of space limitation, and the crossover of the data at high temperatures. This crossover of the experimental isobaric viscosity curves was not confirmed by either the $\text{NO}_2\text{-N}_2\text{O}_4$ or the $\text{NO}_2\text{-N}_2\text{O}_4\text{-NO-O}_2$ equilibrium calculations. Nor is it possible to explain this phenomenon by hypothesizing partial dissociation of the NO_2 to NO and O_2 ,

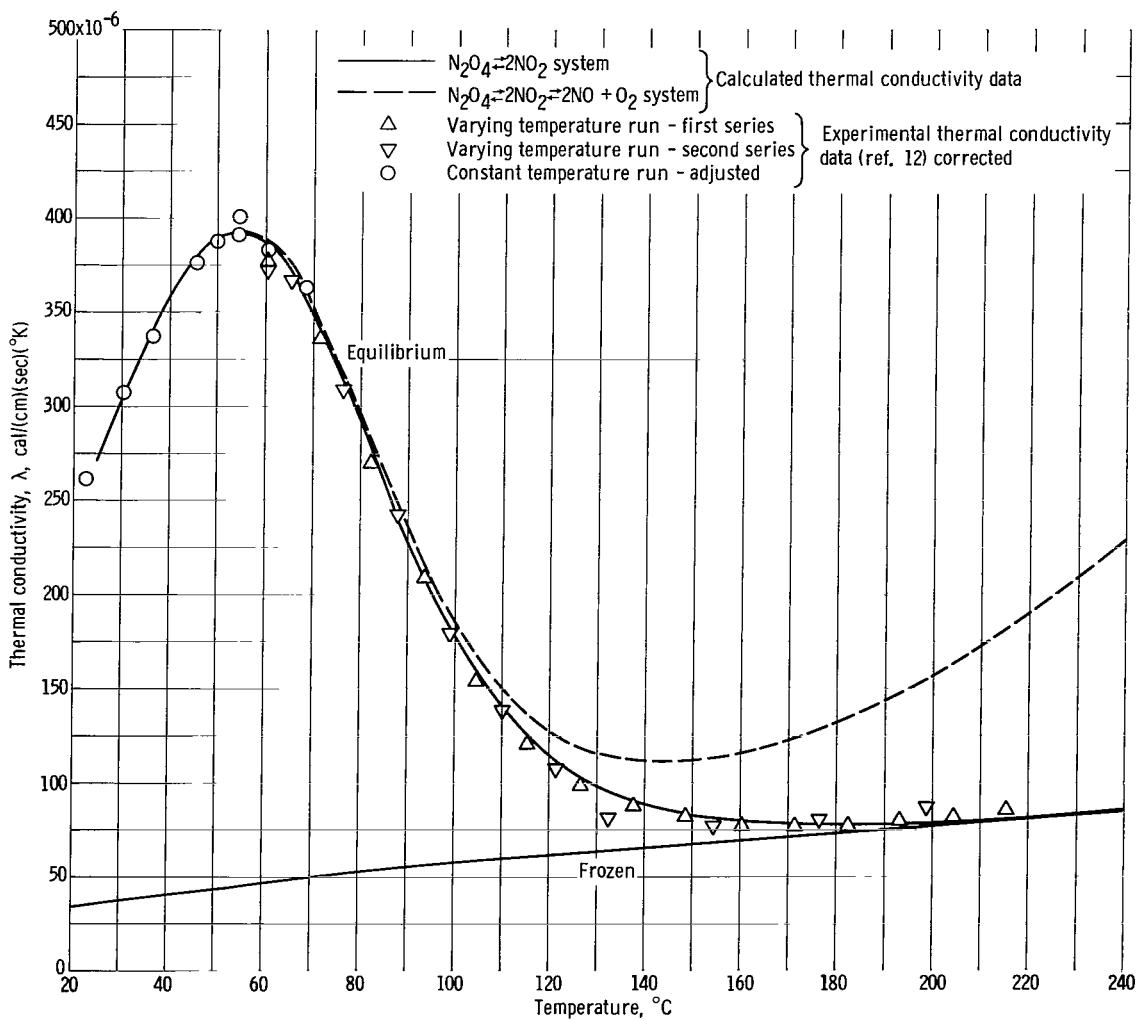

Figure 2. - Experimental and calculated thermal conductivity as a function of temperature at 1 atmosphere.

inasmuch as under the condition most favorable for dissociation (0.5 atm and 170° C) the dissociation at equilibrium would be only 2 percent, as mentioned previously. The calculations of table IV show this is not enough to produce a sufficient change in the viscosity to explain the crossover. Despite the fact that the calculated data did not show this experimentally observed crossover, the standard deviation, in terms of percent of the average experimental viscosity, for all the experimental data was only 0.54 percent. The maximum difference between the experimental and calculated data was 1.20 percent.

Figure 2 shows similar results for frozen and equilibrium thermal conductivities at 1 atmosphere. Included are the experimental data of Coffin and O'Neal (ref. 12). Their data have been corrected for two effects. First, Coffin and O'Neal used the helium conductivity data of Kannuluik and Carman (ref. 28) to calibrate their thermal conductivity cell. An analysis of viscosity and heat conductivity data of helium in terms of rigorous kinetic theory suggests (ref. 29) that Kannuluik and Carman's values are 3 to 5 percent too low. Consequently, the heat conductivities reported by Coffin and O'Neal were corrected as described in reference 21, using the smoothed helium thermal conductivities of reference 29. (The nitrogen thermal conductivities also used in the calibrations of the apparatus described in ref. 12 seem reasonable and were assumed to be correct.)

The second correction accounted for the fact that the reaction $N_2O_4 \rightleftharpoons 2NO_2$ proceeds at a finite rate. The theoretical analysis of reference 27, which studies the effect of geometry, gas phase diffusion and relaxation times, surface reactions, and accommodation coefficients, was applied. Temperature jump at the surface was ignored, and surface reaction was assumed negligible. A discussion of the details of this correction is given in appendix B. Corrections were negligible above about 130° C, and the maximum total correction, which was just under 5 percent, occurred at the peak of the conductivity curve.

Above about 100° C the thermal conductivity curves calculated for the equilibrium $NO_2-N_2O_4$ and $NO_2-N_2O_4-NO-O_2$ curves separate because of the effect of the $NO_2 \rightleftharpoons 2NO+O_2$ reaction on the $NO_2-N_2O_4-NO-O_2$ system. The experimental data clearly tend to follow the $NO_2-N_2O_4$ equilibrium more closely. This would indicate that NO_2 decomposition did not occur rapidly either in the gas phase or on the surfaces. This result is consistent with the values of φ shown in table V of appendix B. Since φ is a measure of the contribution of the gas phase reaction to the thermal conductivity, comparison of φ for the $N_2O_4 \rightleftharpoons 2NO_2$ reaction to the value of φ for the $2NO_2 \rightleftharpoons 2NO+O_2$ reaction represents the relative contribution of each reaction to the reaction conductivity. Since φ for the $N_2O_4 \rightleftharpoons 2NO_2$ reaction is some four orders of magnitude greater than for the $2NO_2 \rightleftharpoons 2NO+O_2$ reaction, the experimental thermal conductivity should be closer to the equilibrium curve in the temperature range where the first reaction is predominant than it should be in the temperature range where the second reaction is predominant. This is observed in figure 2.

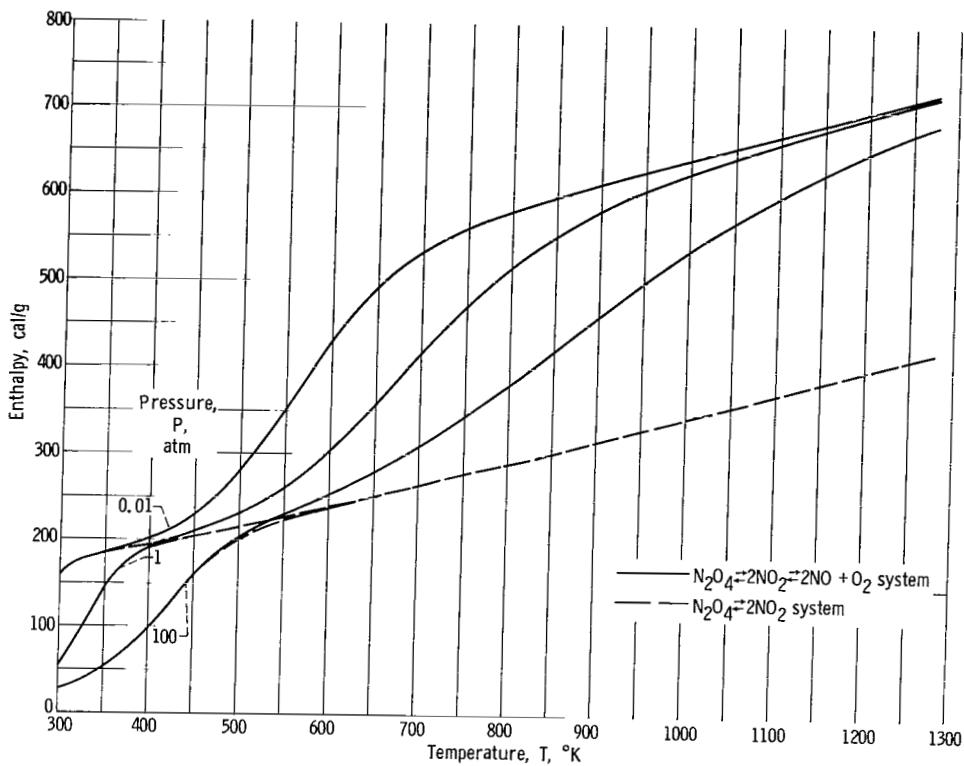

Figure 3. - Enthalpy as a function of temperature.

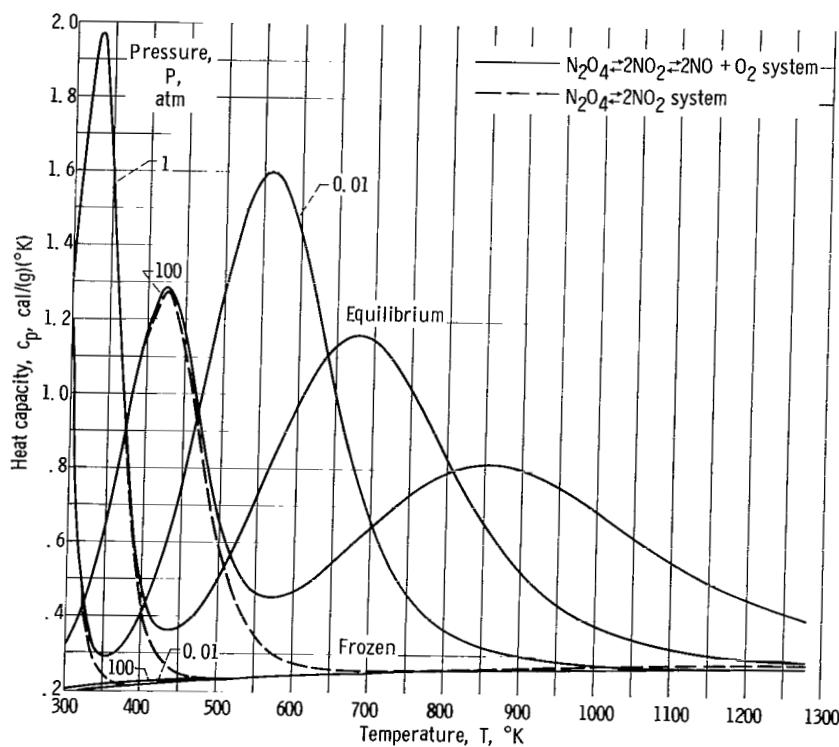

Figure 4. - Heat capacity (c_p) as a function of temperature.

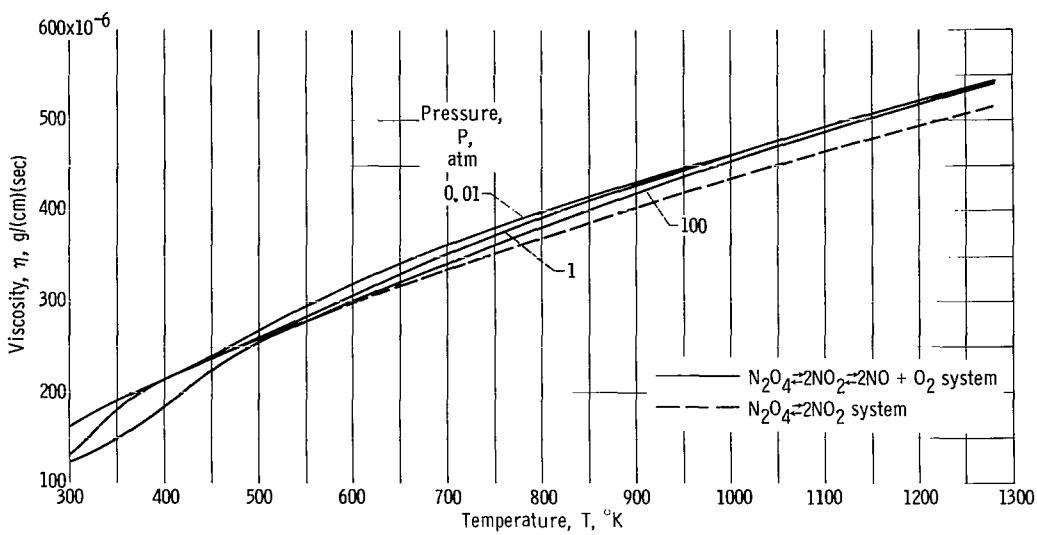

Figure 5. - Viscosity as a function of temperature.

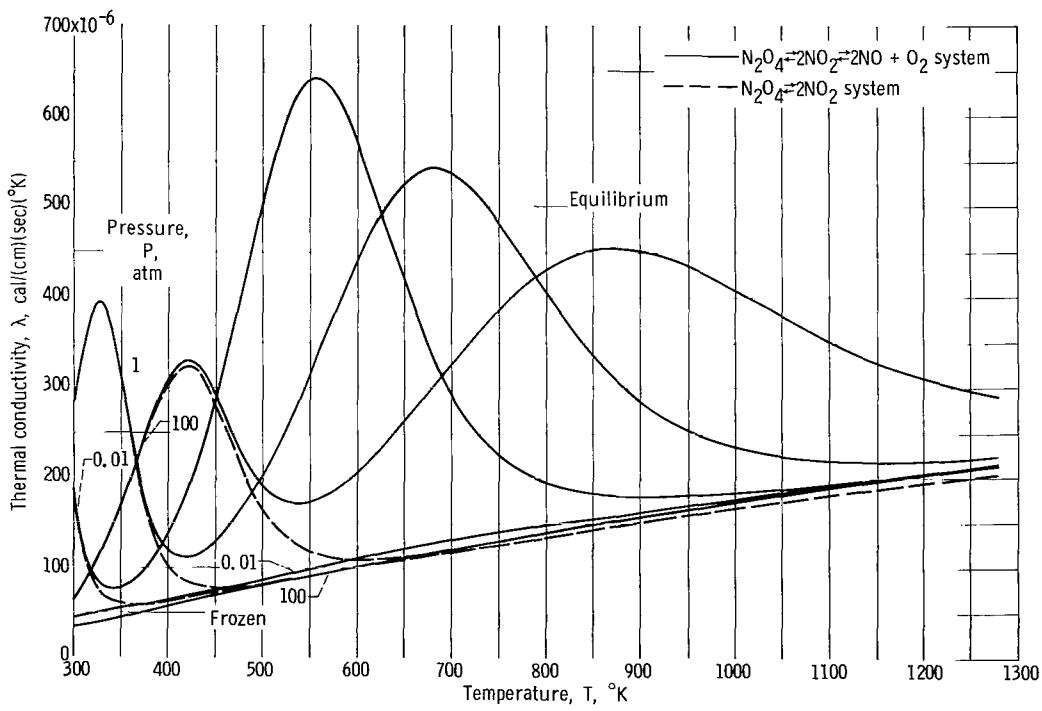

Figure 6. - Thermal conductivity as a function of temperature.

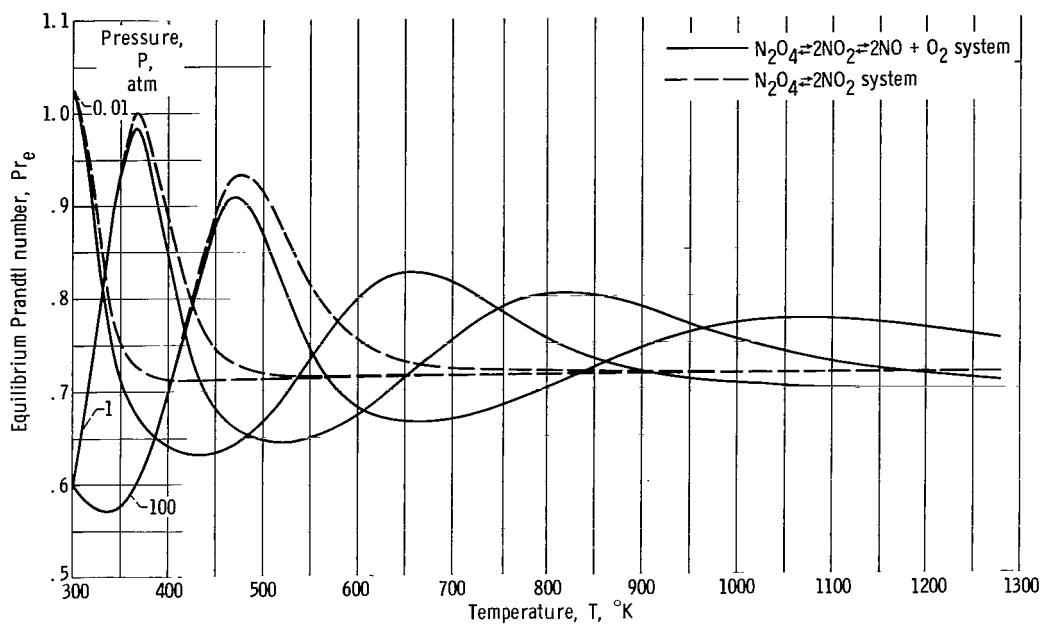

Figure 7. - Equilibrium Prandtl number as a function of temperature.

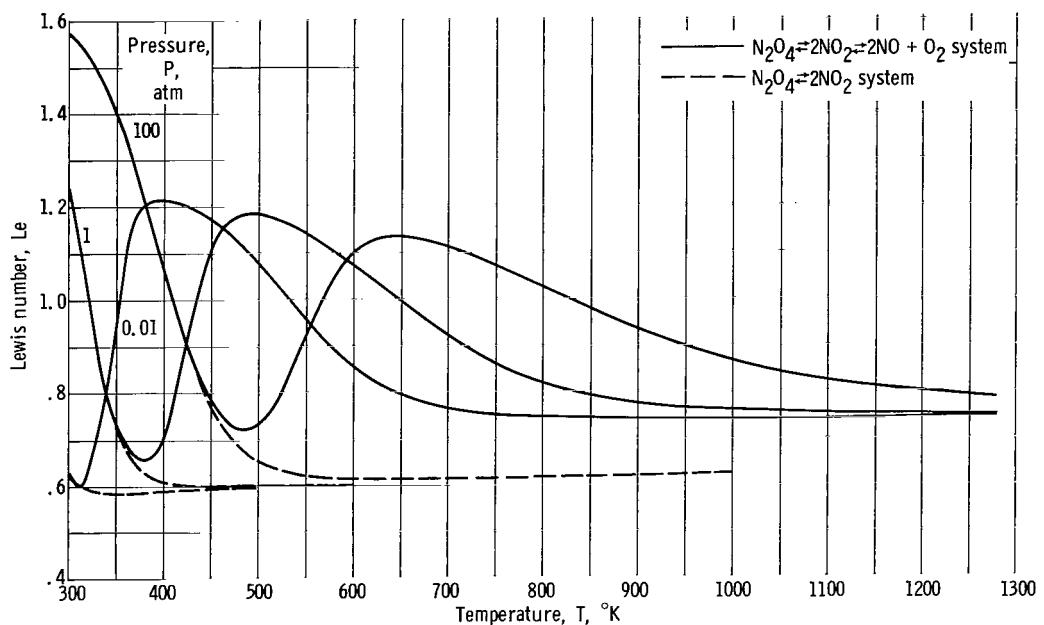

Figure 8. - Lewis number as function of temperature.

Figures 3 to 8 (pp. 10 to 12) show the enthalpy, heat capacity, viscosity, thermal conductivity, Prandtl number, and Lewis number, respectively, at pressures of 0.01, 1, and 100 atmospheres for the NO_2 - N_2O_4 and NO_2 - N_2O_4 - NO - O_2 equilibria. Frozen properties are also included for the enthalpy, heat capacity, viscosity, and thermal conductivity for comparison. The shifting of the curves with changing pressure is caused by the composition changes associated with the pressure change. The curves for the equilibrium thermal conductivity and heat capacity clearly show where the chemical reaction contributes the most. The first peak is due primarily to the $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$ reaction, whereas, the second peak corresponds to the $2\text{NO}_2 \rightleftharpoons 2\text{NO} + \text{O}_2$ reaction.

Because of these peaks the interpolation of the data for the equilibrium heat capacity and thermal conductivity, is rather difficult using standard interpolation equations. Therefore, an interpolation scheme, based on theoretical considerations, is described in appendix D for interpolation of c_{p_r} and λ_r . These two properties may then be added to c_{p_f} and λ_f to obtain c_{p_e} and λ_e , respectively. Properties other than c_{p_r} and λ_r do not show such serious variation with pressure and temperature, and standard interpolation equations may be used.

APPENDIX B

EFFECT OF FINITE REACTION RATE ON THE EQUILIBRIUM THERMAL CONDUCTIVITY FOR THE $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2 \rightleftharpoons 2\text{NO} + \text{O}_2$ SYSTEM

In reference 27 the effective "thermal conductivity" of a reacting gas, ignoring thermal diffusion, is examined for particular geometries that can be described by a single coordinate r . An equation of the following form is developed for a single reversible reaction:

$$\lambda^* = \frac{\lambda_e \lambda_f}{\lambda_f + F\lambda_f + G\lambda_r} \quad (\text{B1})$$

where λ^* is the effective "thermal conductivity" and F and G are functions of the coordinate r , the accommodation coefficients, the surface catalysis, and the reaction rate.

Consider the application of equation (B1) to a hot wire thermal conductivity cell. Assume chemical reactions at the surfaces are negligible and that temperature jump can be ignored. Then, from the results of reference 27 for concentric cylinders, a good approximation of equation (B1) is given by

$$\lambda^* = \frac{\lambda_e}{1 + \frac{K_0(\varphi r_1)}{\varphi r_1 K_1(\varphi r_1) \ln(r_2/r_1)} \left(\frac{\lambda_r}{\lambda_f} \right)} \quad (\text{B2})$$

where r_1 and r_2 are the respective radii of the hot wire and the inner wall of the cell, the K_ν are modified Bessel functions of the second kind of order ν , and φ is given by equation (4). Solving for λ_e results in

$$\lambda_e = \lambda^* \left[1 + \frac{K_0(\varphi r_1)}{\varphi r_1 K_1(\varphi r_1) \ln(r_2/r_1)} \left(\frac{\lambda_r}{\lambda_f} \right) \right] = \lambda^*(1 + \delta) \quad (\text{B3})$$

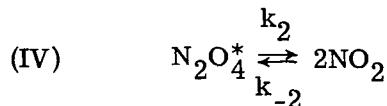

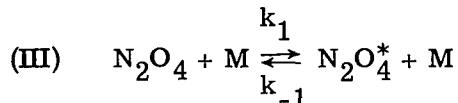

where δ is a correction term. Equation (B3) was used to correct the data of Coffin and O'Neal (ref. 12) for finite reaction rate as follows. For each experimental datum point,

a value of δ was calculated. Then the experimental conductivity λ^* , together with δ , were used to calculate λ_e . These equilibrium thermal conductivity values are the ones shown in figure 2 (p. 8), referred to as experimental data.

For the apparatus of Coffin and O'Neal $r_1 = 6.48 \times 10^{-3}$ centimeter and $r_2/r_1 = 37.1$. The values of φ were calculated from equation (4). Data for λ_e , λ_f , and λ_r were obtained from table IV and the $\Delta H/RT$ were obtained from reference 26. The only other quantity needed to calculate φ was the reaction rate R . The calculation of R involved the following analysis of experimental kinetic data.

Since the reactions $N_2O_4 \rightleftharpoons 2NO_2$ and $2NO + O_2 \rightleftharpoons 2NO_2$ occur simultaneously, the results of reference 27 are not strictly applicable. However, the thermodynamics of the system are such that the first reaction goes almost to completion before the second one becomes important, especially at lower pressure. Furthermore, the kinetics of the reactions (refs. 15, 16, 17, 30, 31, and 32) show that the first is much faster than the second. This means it is possible to ignore the second reaction when considering the first.

Experimental data of Carrington and Davidson on the first reaction (ref. 30) indicate that at high pressure the rate is first order with respect to N_2O_4 , whereas at low pressure the rate is second order. A mechanism for this is suggested from the Lindemann-Hinshelwood theory by the following pair of reactions:

where M is a second body, either a different kind of molecule or another N_2O_4 , and $N_2O_4^*$ is an activated N_2O_4 . The rate of disappearance of N_2O_4 is given by

$$\frac{-d[N_2O_4]}{dt} = k_1[N_2O_4][M] - k_{-1}[N_2O_4^*][M] \quad (B4)$$

where the brackets around the chemical formulas signify concentrations.

If it is assumed that the rate of disappearance of $N_2O_4^*$ is much greater than the rate of formation, the steady state assumption $d[N_2O_4^*]/dt \approx 0$ may be applied, that is,

$$\frac{d[N_2O_4^*]}{dt} = k_1[N_2O_4][M] - k_{-1}[N_2O_4^*][M] - k_2[N_2O_4^*] + k_{-2}[NO_2]^2 = 0 \quad (B5)$$

Solving for $[N_2O_4^*]$, substituting into equation (B4), and then rearranging terms gives

$$-\frac{d[N_2O_4]}{dt} = \left(\frac{k_1}{\frac{k_{-1}}{k_2} [M] + 1} \right) [N_2O_4][M] - \left(\frac{\frac{k_{-2}}{k_2}}{[M] + \frac{k_1}{k_{-1}}} \right) [NO_2]^2[M] \quad (B6)$$

Thus the rate of disappearance of N_2O_4 in the forward direction is

$$\mathcal{R} = \left(\frac{k_1}{\frac{k_{-1}}{k_2} [M] + 1} \right) [N_2O_4][M] \quad (B7)$$

At low pressures the limiting rate is

$$\lim_{[M] \rightarrow 0} \mathcal{R} = k_1[N_2O_4][M] = k_{II}[N_2O_4][M] \quad (B8)$$

where k_{II} is the second order rate constant. At high pressures the limiting rate is

$$\lim_{[M] \rightarrow \infty} \mathcal{R} = \left(\frac{k_2}{k_{-1}} k_1 \right) [N_2O_4] = k_I[N_2O_4] \quad (B9)$$

where k_I is the first order rate constant. Combining these results gives

$$\mathcal{R} = \frac{k_{II}[N_2O_4][M]}{\frac{k_{II}}{k_I} [M] + 1} \quad (B10)$$

Since the value of \mathcal{R} in equation (4) is calculated at equilibrium, the values of $[M]$, which is the total concentration, and $[N_2O_4]$ may be taken from table III. Shock tube studies of the rate of dissociation of N_2O_4 in a large excess of N_2 have given first and

second order rates of $-d[N_2O_4]/dt = 10^{16} \exp(-13\ 000/RT)[N_2O_4]$ and $-d[N_2O_4]/dt = 2 \times 10^{17} \exp(-11\ 000/RT)[N_2O_4][N_2]$ gram-moles per cubic centimeter per second, respectively (ref. 30). The reported first order rate constant was the value used herein. However, other workers have found that NO₂ and N₂O₄ are more efficient second bodies than N₂ (refs. 31 and 32). Their results show that the second order rate constant should be approximately two to three times that found by Carrington and Davidson when NO₂ and N₂O₄ are the second bodies. Furthermore, analysis of experimental thermal conductivity data (ref. 27) suggests a value of about 3.5 times that found in reference 30. In view of these findings a value of 2.5 times that of Carrington and Davidson, namely, $5 \times 10^{17} \exp(-11\ 000/RT)$ cubic centimeter per gram mole per second, was used as an average of the results of various investigators for the calculations herein.

TABLE V. - VALUES OF REACTION RATE PARAMETER φ FOR
VARIOUS PRESSURES^a

				15.9

^aEq. (4), $\varphi \equiv \left[\left(\frac{\lambda_e}{\lambda_f \lambda_r} \right) \left(\frac{\Delta H}{RT} \right)^2 Rg \right]^{1/2}$, cm⁻¹.

At higher temperatures the predominant reaction is $2\text{NO}_2 \rightleftharpoons 2\text{NO} + \text{O}_2$. The rate of dissociation is second order and has been measured by Rosser and Wise (ref. 16) and confirmed by Ashmore and Burnett (ref. 17). Both are consistent with the recalculated work of Bodenstein cited in reference 17. The rate of decomposition of NO_2 is given by

$$-\frac{d[\text{NO}_2]}{dt} = 4 \times 10^{12} \exp\left(-\frac{26900}{RT}\right) [\text{NO}_2]^2 \text{ g-mole/(cc)(sec)} \quad (\text{B11})$$

Table V presents values of φ as calculated from equation (4) at various pressures. The lower temperature values are for the $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$ reaction and the higher temperature values for the $2\text{NO}_2 \rightleftharpoons 2\text{NO} + \text{O}_2$ reaction. Although the reactions are simultaneous, the first reaction is a much faster reaction than the second. Therefore, in most cases the appropriate value of φ is that for the $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$ reaction up to temperatures at which the N_2O_4 is completely dissociated. This was the criterion used in making table V.

APPENDIX C

APPLICATION OF THE CHEMICAL KINETIC PARAMETER φ TO CONVECTIVE HEAT TRANSFER

It is the purpose of this appendix to provide a specific example as to how the chemical kinetic parameter φ , defined in equation (4), may be useful in estimating heat transfer in convective flow where the chemistry is neither completely at equilibrium nor completely frozen.

Consider the Nusselt number formulated with the equilibrium thermal conductivity

$$Nu_e = \frac{hd}{\lambda_e} = \left(\frac{hd}{\lambda^*} \right) \left(\frac{\lambda^*}{\lambda_e} \right) \quad (C1)$$

where h is the heat transfer coefficient, d is a characteristic dimension, and λ^* is the effective "thermal conductivity" of a boundary layer with small temperature differences. It might reasonably be assumed that a heat transfer correlation applicable in the absence of reaction should be appropriate, so that

$$\frac{hd}{\lambda^*} = A \text{ Re}^n \text{ Pr}^m \quad (C2)$$

(For example, if a turbulent pipe flow situation were being considered, $n = 0.8$ and $m \approx 0.3$ to 0.4 .) It may be argued that neither the frozen nor the equilibrium Prandtl number is appropriate for a reacting gas, but rather $\text{Pr} \equiv c_p^* \eta / \lambda^*$ should be used. However, as can be seen from table IV, the equilibrium and frozen Prandtl numbers for a given pressure and temperature are very nearly the same for almost all conditions. Furthermore, the exponent on the Prandtl number is less than one, further reducing the uncertainty in hd/λ^* . Thus, the choice of Prandtl numbers is not critical.

If thermal accommodation occurs on the surface, $F = 0$ in equation (B1) and

$$\frac{\lambda^*}{\lambda_e} = \frac{\lambda_f}{\lambda_f + G\lambda_r} \quad (C3)$$

so that

$$\text{Nu}_e = \frac{A \text{Re}^n \text{Pr}^m}{1 + G \left(\frac{\lambda_r}{\lambda_f} \right)} \quad (\text{C4})$$

Let the boundary layer now be idealized as a stagnant film with heat transfer by conduction only. Then the equations for conduction between plane parallel plates can be applied. It will be assumed that one wall is fully catalytic and corresponds to the free stream or bulk flow, while the other wall is noncatalytic. In this event (ref. 27)

$$G = \frac{\tanh \varphi \ell}{\varphi \ell} \quad (\text{C5})$$

where ℓ is the boundary layer thickness. On the assumption that the heat transfer does occur by conduction through a stagnant film

$$q = h \Delta T = \lambda * \frac{\Delta T}{\ell} \quad (\text{C6})$$

Equations (C2) and (C6) can be combined and solved for ℓ

$$\ell = \frac{d}{A \text{Re}^m \text{Pr}^n} \quad (\text{C7})$$

Thus, the heat transfer coefficient may be obtained through equations (C4), (C5), and (C7). This should be a good approximation for subsonic flows where temperature differences are not too large.

APPENDIX D

INTERPOLATION OF REACTION THERMAL CONDUCTIVITY AND HEAT CAPACITY FOR INTERMEDIATE PRESSURES

From the compositions of table III it is apparent that to a good approximation the reactions $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2 \rightleftharpoons 2\text{NO} + \text{O}_2$ can be treated separately. Then for the first reaction, $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$, the thermal conductivity and heat capacity due to chemical reaction are given by (refs. 22 and 23)

$$\lambda_r = \left(\frac{\Delta H^2}{RT^2} \right) \left(-\frac{PD_{\text{NO}_2-\text{N}_2\text{O}_4}}{R'T} \right) \left[\frac{x_{\text{N}_2\text{O}_4} x_{\text{NO}_2}}{\left(1 + x_{\text{N}_2\text{O}_4}\right)^2} \right] \quad (\text{D1})$$

$$c_{p_r} = \left(\frac{\Delta H^2}{RT^2} \right) \frac{1}{M_{\text{NO}_2}} \left[\frac{x_{\text{N}_2\text{O}_4} x_{\text{NO}_2}}{\left(1 + x_{\text{N}_2\text{O}_4}\right)^3} \right] \quad (\text{D2})$$

At constant temperature, ΔH and $PD_{\text{NO}_2-\text{N}_2\text{O}_4}$ are pressure independent. Therefore, to interpolate for intermediate pressures only the compositions at one known pressure are needed. These can be obtained by solving the following pair of equations:

$$x_{\text{NO}_2} + x_{\text{N}_2\text{O}_4} = 1 \quad (\text{D3})$$

$$\frac{x_{\text{NO}_2}^2 P}{x_{\text{N}_2\text{O}_4}} = K_p \quad (\text{D4})$$

The equilibrium constant in equation (D4) may be calculated at each temperature from the results of table III.

Similar results can be obtained for the $2\text{NO}_2 \rightleftharpoons 2\text{NO} + \text{O}_2$ reaction but are considerably more complicated for λ_r . However, if it is assumed that all three binary diffusion coefficients are the same at each temperature, then

$$\lambda_r \propto \frac{x_{NO_2} x_{NO}}{\left(1 + 0.5 x_{NO_2}\right)^2} \quad (D5)$$

$$c_{p_r} \propto \frac{x_{NO_2}^3 x_{NO}}{\left(1 + 0.5 x_{NO_2}\right)^3} \quad (D6)$$

Similarly, the compositions can be obtained from the following equations:

$$x_{NO_2} + \frac{3}{2} x_{NO} = 1 \quad (D7)$$

$$\frac{\frac{x_{NO}^3 P}{x_{NO_2}^2}}{2K_p} = 2K_p \quad (D8)$$

As an illustration consider the following: Find c_{p_r} at 600° K and 0.3 atmosphere for the equilibrium $NO_2-N_2O_4-NO-O_2$ system.

The solution to this can be found directly from table IV(b), inasmuch as data for 0.3 atmosphere are already tabulated. However, to illustrate the calculating procedure this value will be calculated from the data at 0.1 atmosphere. From equation (D8)

$$2K_p = \frac{x_{NO}^3 P}{x_{NO_2}^2} = \frac{(0.33028)^3 (0.1)}{(0.50457)^2} = 1.41515 \times 10^{-2} \quad (D9)$$

Combining equations (D7) and (D8) gives

$$\frac{x_{NO}^3}{\left(1 - \frac{3}{2} x_{NO}\right)^2} = \frac{2K_p}{P} \quad (D10)$$

To find the composition at 0.3 atmosphere and 600° K, the following is used:

$$\frac{x_{NO}^3}{\left(1 - \frac{3}{2}x_{NO}\right)^2} = \frac{1.41515 \times 10^{-2}}{0.3} = 0.047172 \quad (D11)$$

which is a cubic equation in x_{NO} . Equation (D11) may be solved rather easily by trial and error. For an initial guess, see table III(b). The mole fractions of NO at 0.1 and 1 atmosphere are 0.33028 and 0.19268, respectively. Thus, a first guess for x_{NO} at 0.3 atmosphere will be between these two, perhaps 0.25. By trial and error, it is found that $x_{NO} = 0.25992$, which agrees with that given in table III(b). From equation (D7), $x_{NO_2} = 1 - \frac{3}{2}x_{NO} = 0.61012$. The value of c_{p_r} at 0.1 atmosphere from table IV(b) is $1.3565 - 0.2424 = 1.1141 \text{ cal/(g)(}^{\circ}\text{K)}$. Then applying equation (D6) at 0.1 and 0.3 atmosphere and 600° K, after taking ratios gives

$$\frac{c_{p_r}(0.3 \text{ atm})}{1.1141} = \frac{(0.25992)(0.61012)}{\left[1 + 0.5(0.50457)\right]^3} \frac{\left[1 + 0.5(0.50457)\right]^3}{(0.33028)(0.50457)} \quad (D12)$$

or $c_{p_r} = 0.9367$, which agrees with the value in table IV(b).

TABLE III. - Continued. THERMODYNAMIC PROPERTIES AT ASSIGNED PRESSURE AND TEMPERATURES

[P is pressure, T is temperature, H is enthalpy, S is entropy, $(DLM/DLP)T \equiv (\partial \ln M / \partial \ln P)_T$, $(DLM/DLT)P \equiv (\partial \ln M / \partial \ln T)_P$, CP is heat capacity at constant pressure, and GAMMA is isentropic exponent $(\partial \ln P / \partial \ln \rho)_S$ where ρ is density.]

(a) Continued. NO₂-N₂O₄ system

TABLE III. - Continued. THERMODYNAMIC PROPERTIES AT ASSIGNED PRESSURE AND TEMPERATURES

[P is pressure, T is temperature, H is enthalpy, S is entropy, $(DLM/DLP)T = (\partial \ln M / \partial \ln P)_T$, $(DLM/DLT)P = (\partial \ln M / \partial \ln T)_P$, CP is heat capacity at constant pressure, and GAMMA is isentropic exponent $(\partial \ln P / \partial \ln \rho)_S$ where ρ is density.]

(b) Continued. $\text{NO}_2\text{-N}_2\text{O}_4\text{-NO-O}_2$ system

TABLE III. - Continued, THERMODYNAMIC PROPERTIES AT ASSIGNED PRESSURE AND TEMPERATURES

[P is pressure, T is temperature, H is enthalpy, S is entropy, $(DLM/DLP)T = (\partial \ln M / \partial \ln P)_T$, $(DLM/DLT)P = (\partial \ln M / \partial \ln T)_P$, CP is heat capacity at constant pressure, and GAMMA is isentropic exponent ($\partial \ln P / \partial \ln \rho$)_S where ρ is density.]

(b) Continued. NO₂-N₂O₄-NO-O₂ system

TABLE III. - Continued. THERMODYNAMIC PROPERTIES AT ASSIGNED PRESSURE AND TEMPERATURES

[P is pressure, T is temperature, H is enthalpy, S is entropy, $(DLM/DLP)T = (\partial \ln M / \partial \ln P)_T$, $(DLM/DLT)P = (\partial \ln M / \partial \ln T)_P$, CP is heat capacity at constant pressure, and GAMMA is isentropic exponent $(\partial \ln P / \partial \ln \rho)_S$ where ρ is density.]

(b) Continued. $\text{NO}_2\text{-N}_2\text{O}_4\text{-NO-O}_2$ system

TABLE III. - Concluded. THERMODYNAMIC PROPERTIES AT ASSIGNED PRESSURE AND TEMPERATURES

[P is pressure, T is temperature, H is enthalpy, S is entropy, $(DLM/DLP)T = (\partial \ln M / \partial \ln P)_T$, $(DLM/DLT)P = (\partial \ln M / \partial \ln T)_P$, CP is heat capacity at constant pressure, and GAMMA is isentropic exponent ($\partial \ln P / \partial \ln \rho$)_S where ρ is density.]

(b) Concluded. NO₂-N₂O₄-NO-O₂ system

"The aeronautical and space activities of the United States shall be conducted so as to contribute . . . to the expansion of human knowledge of phenomena in the atmosphere and space. The Administration shall provide for the widest practicable and appropriate dissemination of information concerning its activities and the results thereof."

—NATIONAL AERONAUTICS AND SPACE ACT OF 1958

NASA SCIENTIFIC AND TECHNICAL PUBLICATIONS

TECHNICAL REPORTS: Scientific and technical information considered important, complete, and a lasting contribution to existing knowledge.

TECHNICAL NOTES: Information less broad in scope but nevertheless of importance as a contribution to existing knowledge.

TECHNICAL MEMORANDUMS: Information receiving limited distribution because of preliminary data, security classification, or other reasons.

CONTRACTOR REPORTS: Technical information generated in connection with a NASA contract or grant and released under NASA auspices.

TECHNICAL TRANSLATIONS: Information published in a foreign language considered to merit NASA distribution in English.

TECHNICAL REPRINTS: Information derived from NASA activities and initially published in the form of journal articles.

SPECIAL PUBLICATIONS: Information derived from or of value to NASA activities but not necessarily reporting the results of individual NASA-programmed scientific efforts. Publications include conference proceedings, monographs, data compilations, handbooks, sourcebooks, and special bibliographies.

Details on the availability of these publications may be obtained from:
